# Total momentum conservation and statistical studies of jets

- A few useful definitions and properties
  - probability distributions, cumulants, generating functions...
- Multiparticle correlation induced by total momentum conservation
  - a general, model-independent calculation

Eur. Phys. J. C 30 (2003) 381

- Specific study of two- and three-particle correlations due to total momentum conservation

Phys. Rev. C 75 (2007) 021904(R)

# A well-defined mathematical problem...

Consider a **finite-size- $N$  ring polymer** (in a  $D$ -dimensional space):  
"closed":  $\mathbf{p}_1 + \mathbf{p}_2 + \cdots + \mathbf{p}_N = \mathbf{0}$

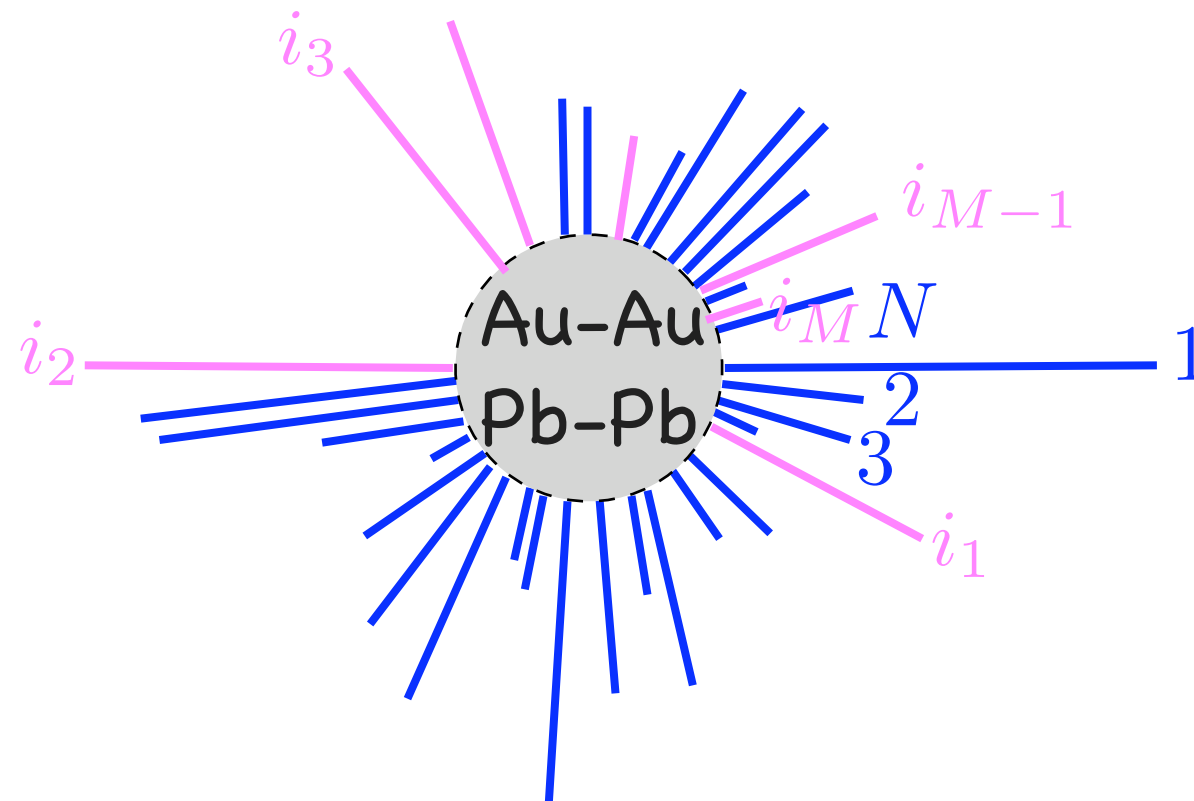

Take  $M$  monomers among the  $N$  ones.

What is the multiple correlation induced between these monomers by the overall constraint  $\mathbf{p}_1 + \mathbf{p}_2 + \cdots + \mathbf{p}_N = \mathbf{0}$ ?

# A well-defined mathematical problem...

Consider  $N$  particles constrained by (total) momentum conservation:  
for instance, in the center-of-mass frame of the colliding nuclei, the  $N$  particles emitted in a Au-Au collision satisfy  $\mathbf{p}_1 + \mathbf{p}_2 + \dots + \mathbf{p}_N = \mathbf{0}$ .

What is the correlation between  $M$  arbitrary particles induced by the momentum-conservation constraint?

# Multiparticle correlations & cumulants

•  $M$ -particle probability distribution  $f(\mathbf{p}_{i_1}, \dots, \mathbf{p}_{i_M})$ :

probability that particles  $\{i_1, i_2, \dots, i_M\}$  have momenta  $\mathbf{p}_{i_1}, \mathbf{p}_{i_2}, \dots, \mathbf{p}_{i_M}$  irrespective of the momenta of the  $N - M$  other particles.

👉 normalized to unity:  $f(\{\mathbf{p}_{i_k}\}) = \mathcal{O}(1), \forall M$

Generating function of the probability distribution:

$$G(x_1, \dots, x_N) = 1 + x_1 f(\mathbf{p}_1) + x_2 f(\mathbf{p}_2) + \dots + x_1 x_2 f(\mathbf{p}_1, \mathbf{p}_2) + \dots$$

$x_1, \dots, x_N$  auxiliary (complex) variables

Independent particles:  $f(\mathbf{p}_1, \mathbf{p}_2, \dots, \mathbf{p}_N) = f(\mathbf{p}_1) f(\mathbf{p}_2) \cdots f(\mathbf{p}_N)$

# Multiparticle correlations & cumulants

- $M$ -particle cumulant of the probability distribution  $f_c(\mathbf{p}_{i_1}, \dots, \mathbf{p}_{i_M})$ : connected part of the probability distribution, responsible for the "correlations" (= deviations from statistical independence)

$$f(\mathbf{p}_1, \mathbf{p}_2) = f_c(\mathbf{p}_1) f_c(\mathbf{p}_2) + f_c(\mathbf{p}_1, \mathbf{p}_2)$$

(note:  $f(\mathbf{p}) = f_c(\mathbf{p}) \dots$ )

At the three-particle level:

Generating function of the cumulants: 😊

$$\ln G(x_1, \dots, x_N) = 1 + x_1 f_c(\mathbf{p}_1) + x_2 f_c(\mathbf{p}_2) + \dots + x_1 x_2 f_c(\mathbf{p}_1, \mathbf{p}_2) + \dots$$

# Multiparticle correlations & cumulants

How do cumulants scale with the total multiplicity  $N$ ?

For a system made of independent sub-systems (or with short-range correlations), the probability distributions add up:

$$f(\{\mathbf{p}_j\}) = \sum_A \frac{N_A}{N} f_A(\{\mathbf{p}_j\}) \quad \text{i.e.} \quad G(\{x_j\}) = \prod_A g_A \left( \left\{ \frac{N_A x_j}{N} \right\} \right)$$

At the cumulant level,  $\ln G(\{x_j\}) = \sum_A \ln g_A \left( \left\{ \frac{N_A x_j}{N} \right\} \right)$

Expand, search for the coefficient of  $x_{i_1} \dots x_{i_M}$

$$\text{👉 } f_c(\mathbf{p}_{i_1}, \dots, \mathbf{p}_{i_M}) = \mathcal{O} \left( \frac{1}{N^{M-1}} \right)$$

What about the case of particles whose momenta are constrained by total momentum conservation?

# Total momentum conservation and $M$ -particle distribution

In the presence of the **constraint** from **total momentum conservation**,  
the  $M$ -particle distribution reads:

single-particle distribution  
in the absence of **constraint**

normalization constant

$$f(\mathbf{p}_1, \dots, \mathbf{p}_M) \equiv \frac{\left( \prod_{j=1}^M F(\mathbf{p}_j) \right) \int \delta^D(\mathbf{p}_1 + \dots + \mathbf{p}_N) \prod_{j=M+1}^N [F(\mathbf{p}_j) d^D \mathbf{p}_j] / \mathcal{N}_D^{N-M}}{\int \delta^D(\mathbf{p}_1 + \dots + \mathbf{p}_N) \prod_{j=1}^N [F(\mathbf{p}_j) d^D \mathbf{p}_j] / \mathcal{N}_D^N}$$

$M$ -independent denominator  $\equiv 1/\mathcal{C}_D$

which one then inserts in the **generating function**...

# Total momentum conservation and $M$ -particle distribution

In the presence of the **constraint** from **total momentum conservation**,  
the  $M$ -particle distribution reads:

single-particle distribution  
in the absence of **constraint**

normalization constant

$$f(\mathbf{p}_1, \dots, \mathbf{p}_M) \equiv \frac{\left( \prod_{j=1}^M F(\mathbf{p}_j) \right) \int \delta^D(\mathbf{p}_1 + \dots + \mathbf{p}_N) \prod_{j=M+1}^N [F(\mathbf{p}_j) d^D \mathbf{p}_j] / \mathcal{N}_D^{N-M}}{\int \delta^D(\mathbf{p}_1 + \dots + \mathbf{p}_N) \prod_{j=1}^N [F(\mathbf{p}_j) d^D \mathbf{p}_j] / \mathcal{N}_D^N}$$

$$M\text{-independent denominator} \equiv 1/C_D = \int \frac{d^D \mathbf{k}}{(2\pi)^D} \prod_{j=1}^N e^{i\mathbf{k} \cdot \mathbf{p}_j}$$

which one then inserts in the **generating function**...

# Generating function

Introducing the notation  $\langle g(\mathbf{p}) \rangle \equiv \int g(\mathbf{p}) F(\mathbf{p}) d^D \mathbf{p} / \mathcal{N}_D$ , one finds:

$$\begin{aligned}
 G(x_1, \dots, x_N) &= C_D \int \frac{d^D \mathbf{k}}{(2\pi)^D} \langle e^{i\mathbf{k} \cdot \mathbf{p}} \rangle^N \exp \left( \sum_{j=1}^N x_j F(\mathbf{p}_j) \frac{e^{i\mathbf{k} \cdot \mathbf{p}_j}}{\langle e^{i\mathbf{k} \cdot \mathbf{p}} \rangle} \right) \\
 &= C_D \int \frac{d^D \mathbf{k}}{(2\pi)^D} \exp \left[ N \left( \ln \langle e^{i\mathbf{k} \cdot \mathbf{p}} \rangle + \sum_{j=1}^N \frac{\bar{x}_j}{N} \frac{e^{i\mathbf{k} \cdot \mathbf{p}_j}}{\langle e^{i\mathbf{k} \cdot \mathbf{p}} \rangle} \right) \right]
 \end{aligned}$$

the unmeasurable  $F$  is absorbed

$\mathcal{F}(\mathbf{k})$

only depends on  $\frac{x}{N}$

I shall show (using a saddle-point method) that

$$G(x_1, \dots, x_N) \propto e^{N \mathcal{F}(\mathbf{k}_0)} \left( 1 + \sum_{q>l} \frac{x^l}{N^q} \right)$$

# Saddle-point method

A Taylor expansion around the saddle-point  $\mathbf{k}_0$  yields

$$G(x_1, \dots, x_N) = C_D e^{N\mathcal{F}(\mathbf{k}_0)} \left( \sum \text{Gaussian integrals} \right)$$

$$\frac{1}{N^{D/2}} \int \frac{d^D \kappa}{(2\pi)^D} e^{-\mathcal{F}''(\mathbf{k}_0) \kappa^2 / 2} \exp \left[ \sum_{m \geq 3} \frac{\mathcal{F}^{(m)}(\mathbf{k}_0)}{m!} \frac{\kappa^m}{N^{m/2-1}} \right]$$

$\underbrace{\frac{1}{N^{D/2}} \int \frac{d^D \kappa}{(2\pi)^D} e^{-\mathcal{F}''(\mathbf{k}_0) \kappa^2 / 2}}_1$

$\underbrace{\frac{1}{[2\pi \mathcal{F}''(\mathbf{k}_0)]^{D/2}}}_{\text{only depend on } \frac{x}{N}} \leq 1/\sqrt{N}$

Therefore  $G(x_1, \dots, x_N) = \frac{C_D e^{N\mathcal{F}(\mathbf{k}_0)}}{[2\pi N \mathcal{F}''(\mathbf{k}_0)]^{D/2}} \left( 1 + \sum_{q>l} \frac{x^l}{N^q} \right)$

# Cumulants

The generating function of cumulants thus reads

$$\ln G(x_1, \dots, x_N) = \ln C_D + \underbrace{N \mathcal{F}(\mathbf{k}_0)}_{\text{function of } \frac{x}{N}} + \ln \left( \text{function of } \frac{x^l}{N^{q \geq l}} \right)$$

independent of  $x$   $\nearrow$

$\mathcal{F}$  only depends on  $\frac{x}{N}$   $\swarrow$   $\mathbf{k}_0$  function of  $\frac{x}{N}$   
 (solution of  $\mathcal{F}'(\mathbf{k}_0) = 0$ )

Hence the cumulants:

$$f_c(\mathbf{p}_{i_1}, \dots, \mathbf{p}_{i_M}) = \text{coef. of } x_{i_1} \cdots x_{i_M} \text{ in } N \mathcal{F}(\mathbf{k}_0) + \mathcal{O}\left(\frac{1}{N^M}\right) = \mathcal{O}\left(\frac{1}{N^{M-1}}\right)$$

The cumulants arising from **total momentum conservation** follow the same scaling behaviour as those from **short-range correlations**!

👉 nice for “cumulant” or “Lee-Yang zeroes” methods of **anisotropic-flow** analysis

# Computing the first cumulants

- The saddle-point is given by  $\mathcal{F}'(\mathbf{k}_0) = 0$ , i.e.

$$\left( \sum_{j=1}^N \frac{x_j}{N} \frac{e^{i\mathbf{k}_0 \cdot \mathbf{p}_j}}{\langle e^{i\mathbf{k}_0 \cdot \mathbf{p}} \rangle} - 1 \right) \langle \mathbf{p} e^{i\mathbf{k}_0 \cdot \mathbf{p}} \rangle = \sum_{j=1}^N \frac{x_j}{N} \mathbf{p}_j e^{i\mathbf{k}_0 \cdot \mathbf{p}_j}$$

- The cumulants are given by  $\ln G(x_1, \dots, x_N) = N\mathcal{F}(\mathbf{k}_0)$

To lowest order\*,  $i\mathbf{k}_0 = -\frac{D}{\langle \mathbf{p}^2 \rangle} \sum_{j=1}^N \frac{x_j}{N} \mathbf{p}_j$ , hence

$$\mathcal{F}(\mathbf{k}_0) = \sum_{j=1}^N \frac{x_j}{N} - \frac{D}{2\langle \mathbf{p}^2 \rangle} \left( \sum_{j=1}^N \frac{x_j}{N} \mathbf{p}_j \right)^2$$

which gives  $f_c(\mathbf{p}_1, \mathbf{p}_2) = -\frac{D \mathbf{p}_1 \cdot \mathbf{p}_2}{N \langle \mathbf{p}^2 \rangle}$ , of order  $\mathcal{O}\left(\frac{1}{N}\right)$  as expected

\* assuming  $F(\mathbf{p})$  isotropic, so that  $\langle \mathbf{p} \rangle = 0$  and  $\langle (\mathbf{k}_0 \cdot \mathbf{p})^2 \rangle = \mathbf{k}_0^2 \langle \mathbf{p}^2 \rangle / D$

# Computing the first cumulants

Going to the next order in  $\frac{x}{N}$ :

$$i\mathbf{k}_0 = - \left[ 1_D - \left( X_0 1_D - \frac{D}{\langle \mathbf{p}^2 \rangle} X_2 \right) \right]^{-1} \frac{D}{\langle \mathbf{p}^2 \rangle} \mathbf{X}_1$$

unit  $D \times D$  matrix  $\nearrow$

$$\text{with } X_0 \equiv \sum_{j=1}^N \frac{x_j}{N}, \quad \mathbf{X}_1 \equiv \sum_{j=1}^N \frac{x_j}{N} \mathbf{p}_j, \quad X_2 \equiv \sum_{j=1}^N \frac{x_j}{N} \mathbf{p}_j \otimes \mathbf{p}_j$$

$$\mathcal{F}(\mathbf{k}_0) = X_0 - \frac{D}{2\langle \mathbf{p}^2 \rangle} (\mathbf{X}_1)^2 - \frac{D}{2\langle \mathbf{p}^2 \rangle} \mathbf{X}_1 \cdot \left( X_0 1_D - \frac{D}{\langle \mathbf{p}^2 \rangle} X_2 \right) \cdot \mathbf{X}_1$$

$$\ln G(x_1, \dots, x_N) = \sum_{j=1}^N x_j \left[ -\frac{D}{2N\langle \mathbf{p}^2 \rangle} \sum_{j,k} x_j x_k (\mathbf{p}_j \cdot \mathbf{p}_k) \right. \\ \left. - \frac{D}{2N^2\langle \mathbf{p}^2 \rangle} \sum_{j,k,l} x_j x_k x_l \left[ \mathbf{p}_j \cdot \mathbf{p}_l - \frac{D}{\langle \mathbf{p}^2 \rangle} (\mathbf{p}_j \cdot \mathbf{p}_k)(\mathbf{p}_k \cdot \mathbf{p}_l) \right] \right]$$

2-particle cumulants

3-particle cumulants:  $\mathcal{O}(1/N^2)$ !

# Total momentum conservation and $M$ -particle cumulants

Using a saddle-point method (which implies  $N \gg 1$ ), I have computed in a model-independent way the multiparticle cumulants arising from the constraint  $\mathbf{p}_1 + \mathbf{p}_2 + \dots + \mathbf{p}_N = \mathbf{0}$

$$f_c(\mathbf{p}_1, \mathbf{p}_2) = -\frac{D \mathbf{p}_1 \cdot \mathbf{p}_2}{N \langle \mathbf{p}^2 \rangle}$$

will be taken =2 in what follows  
(transverse momentum conservation)

$$f_c(\mathbf{p}_1, \mathbf{p}_2, \mathbf{p}_3) = -\frac{D}{N^2 \langle \mathbf{p}^2 \rangle} (\mathbf{p}_1 \cdot \mathbf{p}_2 + \mathbf{p}_1 \cdot \mathbf{p}_3 + \mathbf{p}_2 \cdot \mathbf{p}_3) \\ + \frac{D^2}{N^2 \langle \mathbf{p}^2 \rangle^2} [(\mathbf{p}_1 \cdot \mathbf{p}_2)(\mathbf{p}_1 \cdot \mathbf{p}_3) + (\mathbf{p}_1 \cdot \mathbf{p}_2)(\mathbf{p}_2 \cdot \mathbf{p}_3) \\ + (\mathbf{p}_1 \cdot \mathbf{p}_3)(\mathbf{p}_2 \cdot \mathbf{p}_3)]$$

Moreover, the  $M$ -particle cumulant arising from the conservation of total momentum scales with multiplicity as  $1/N^{M-1}$ , as those from short-range correlations!

# Two-particle correlation due to total transverse momentum conservation

We have seen that  $f_c(\mathbf{p}_1, \mathbf{p}_2) = -\frac{2\mathbf{p}_1 \cdot \mathbf{p}_2}{N\langle \mathbf{p}^2 \rangle}$ , which means that the two-particle probability distribution reads

$$f(\mathbf{p}_1, \mathbf{p}_2) = f(\mathbf{p}_1)f(\mathbf{p}_2) \left( 1 - \frac{2p_1p_2 \cos(\varphi_2 - \varphi_1)}{N\langle \mathbf{p}^2 \rangle} \right)$$

Thus, if there is a first particle with transverse momentum  $\mathbf{p}_1$ , then the probability to find a second particle with transverse momentum  $\mathbf{p}_2$  is NOT isotropic, but larger "away" (in azimuth) from  $\mathbf{p}_1$ .

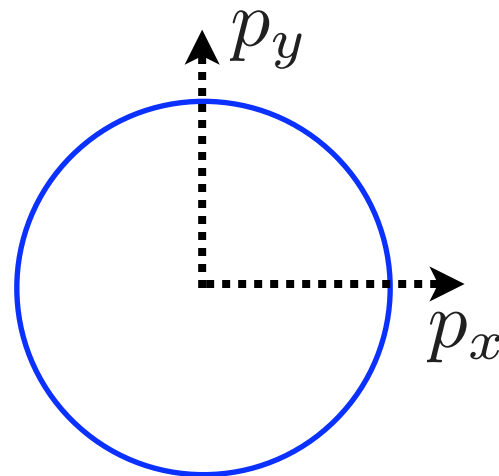

# Two-particle correlation due to total transverse momentum conservation

We have seen that  $f_c(\mathbf{p}_1, \mathbf{p}_2) = -\frac{2\mathbf{p}_1 \cdot \mathbf{p}_2}{N\langle \mathbf{p}^2 \rangle}$ , which means that the two-particle probability distribution reads

$$f(\mathbf{p}_1, \mathbf{p}_2) = f(\mathbf{p}_1)f(\mathbf{p}_2) \left( 1 - \frac{2p_1p_2 \cos(\varphi_2 - \varphi_1)}{N\langle \mathbf{p}^2 \rangle} \right)$$

Thus, if there is a first particle with transverse momentum  $\mathbf{p}_1$ , then the probability to find a second particle with transverse momentum  $\mathbf{p}_2$  is NOT isotropic, but larger "away" (in azimuth) from  $\mathbf{p}_1$ .

# Two-particle correlation due to total transverse momentum conservation

We have seen that  $f_c(\mathbf{p}_1, \mathbf{p}_2) = -\frac{2\mathbf{p}_1 \cdot \mathbf{p}_2}{N\langle \mathbf{p}^2 \rangle}$ , which means that the two-particle probability distribution reads

$$f(\mathbf{p}_1, \mathbf{p}_2) = f(\mathbf{p}_1)f(\mathbf{p}_2) \left( 1 - \frac{2p_1p_2 \cos(\varphi_2 - \varphi_1)}{N\langle \mathbf{p}^2 \rangle} \right)$$

Thus, if there is a first particle with transverse momentum  $\mathbf{p}_1$ , then the probability to find a second particle with transverse momentum  $\mathbf{p}_2$  is NOT isotropic, but larger "away" (in azimuth) from  $\mathbf{p}_1$ .

# Two-particle correlation due to total transverse momentum conservation

We have seen that  $f_c(\mathbf{p}_1, \mathbf{p}_2) = -\frac{2\mathbf{p}_1 \cdot \mathbf{p}_2}{N\langle \mathbf{p}^2 \rangle}$ , which means that the two-particle probability distribution reads

$$f(\mathbf{p}_1, \mathbf{p}_2) = f(\mathbf{p}_1)f(\mathbf{p}_2) \left( 1 - \frac{2p_1p_2 \cos(\varphi_2 - \varphi_1)}{N\langle \mathbf{p}^2 \rangle} \right)$$

Thus, if there is a first particle with transverse momentum  $\mathbf{p}_1$ , then the probability to find a second particle with transverse momentum  $\mathbf{p}_2$  is NOT isotropic, but larger “away” (in azimuth) from  $\mathbf{p}_1$ .

One cannot speak of “a jet + an (uncorrelated) background event”!

# Two-particle correlation due to total transverse momentum conservation

The conservation of total transverse momentum does correlate all particles in the event together!

$$f_c(\mathbf{p}_1, \mathbf{p}_2) = -\frac{D \mathbf{p}_1 \cdot \mathbf{p}_2}{N \langle \mathbf{p}^2 \rangle}$$

The correlation is back-to-back, & larger between particles with larger momenta

👉 should not be forgotten in jet studies...

Its meaning?

That the conditional probability for an “associated” particle to have a momentum  $\mathbf{p}_2$  when there is a “trigger” particle with momentum  $\mathbf{p}_1$  is not the same as the probability to have a particle with momentum  $\mathbf{p}_2$  irrespective of the momenta of the other particles.

The “background” to the jet is modulated by its presence (need to balance the momentum).

# Total momentum conservation and statistical studies of jets

The “background” to the jet is modulated by its presence (need to balance the momentum).

This is a model-independent statement! I do not assume any specific micro-/macroscopic picture of the correlation between the jet and the other particles.

👉 issue for methods which decompose the event into jet+background, as they might not be easy to disentangle from each other.

Safer approach (cf. Claude Pruneau!):

- ◆ measure the cumulants on the one hand;
- ◆ compute their values due to various sources of correlation on the other hand.

# Three-particle correlation due to total transverse momentum conservation

$$f_c(\mathbf{p}_1, \mathbf{p}_2, \mathbf{p}_3) = \underbrace{-\frac{D}{N^2 \langle \mathbf{p}^2 \rangle} (\dots)}_{\text{repulsive term}} + \underbrace{\frac{D^2}{N^2 \langle \mathbf{p}^2 \rangle^2} (\dots)}_{\text{attractive term}}$$

The attractive term dominates over the first one when all three particles have transverse momenta larger than the rms transverse momentum: relevant case for high- $p_T$  studies!

Let us investigate the behaviour of this cumulant!

(for simplicity, in the case  $p_{\text{trigger}} \equiv p_1 > p_2 = p_3 \equiv p_{\text{assoc.}}$ .)

I shall use the relative angles  $\Delta\varphi_{12} \equiv \varphi_1 - \varphi_2$  and  $\Delta\varphi_{13} \equiv \varphi_1 - \varphi_3$

# Three-particle correlation due to total transverse momentum conservation

RHIC-inspired values:  $N = 8000$  particles,  $\langle p^2 \rangle^{1/2} = 0.45$  GeV

$$p_1 = 3.2 \text{ GeV}, \quad p_2 = p_3 = 1.2 \text{ GeV}$$

same size as correlations due to flow

Note the 2 humps around  $180^\circ$

# Three-particle correlation due to total transverse momentum conservation

RHIC-inspired values:  $N = 8000$  particles,  $\langle p^2 \rangle^{1/2} = 0.45$  GeV

$$p_1 = 3.2 \text{ GeV}, \quad p_2 = p_3 = 1.2 \text{ GeV}$$

$$\Delta\varphi_{12} = \Delta\varphi_{13}$$

(Local) maximum at  $180^\circ$

$$\Delta\varphi_{12} = \pi - \Delta\varphi_{13}$$

Two humps around  $180^\circ$

# Three-particle correlation due to total transverse momentum conservation

RHIC-inspired values:  $N = 8000$  particles,  $\langle p^2 \rangle^{1/2} = 0.45$  GeV

$$p_1 = 6 \text{ GeV} \geq 5(p_2 = p_3) = 1.2 \text{ GeV}$$

correlations are larger

The 2 humps around  $180^\circ$  have merged into one

# Three-particle correlation due to total transverse momentum conservation

RHIC-inspired values:  $N = 8000$  particles,  $\langle p^2 \rangle^{1/2} = 0.45$  GeV

$$p_1 = 6 \text{ GeV} \geq 5(p_2 = p_3) = 1.2 \text{ GeV}$$

$$\Delta\varphi_{12} = \Delta\varphi_{13}$$

(Local) maximum at  $180^\circ$

$$\Delta\varphi_{12} = \pi - \Delta\varphi_{13}$$

One big hump at  $180^\circ$

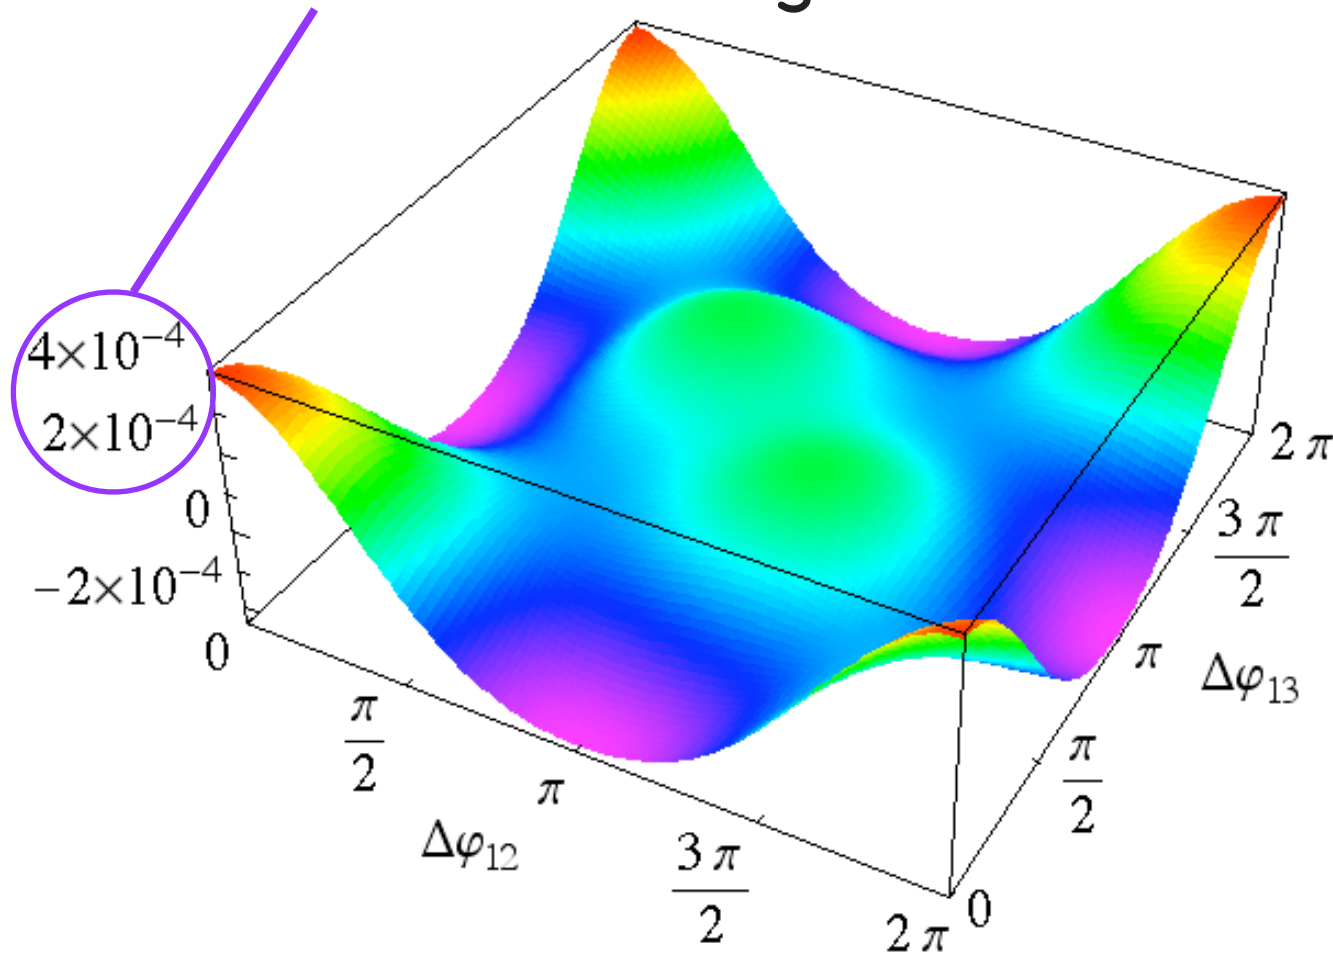

The structure away from the "trigger" depends on the cuts

# Three-particle correlation due to total transverse momentum conservation

SPS-inspired values:  $N = 2500$  particles,  $\langle p^2 \rangle^{1/2} = 0.45$  GeV

$$p_1 = 3.2 \text{ GeV}, \quad p_2 = p_3 = 1.2 \text{ GeV}$$

correlations are larger than at RHIC

# Total momentum conservation and statistical studies of jets

Total momentum conservation induces correlations between the particles emitted in a collision.

These correlations can be computed... and their value can be estimated if one “knows” the total emitted multiplicity  $N$  and the mean square momentum  $\langle p^2 \rangle$ .

👉 can be treated as parameters

Do not underestimate its possible role!
